## Problem 1

We assume the only change in the physical distance between the test particles is due to the change in the scale factor. In a vacuum dominated universe, the scale factor grows as

$$a(t) = a_0 e^{Ht},$$

where  $H$  is the Hubble parameter. The physical distance between the test particles is

$$d(t) = a(t)r(t),$$

where  $r(t)$  is the coordinate separation, which does not change under evolution due only to the scale factor. The physical separation between the particles is then

$$d(t) = r_0 e^{Ht}.$$

The time for a given relative change in physical separation is therefore

$$t = H^{-1} \ln\left(\frac{d}{r_0}\right).$$

For movement on the order of the initial separation size (i.e.  $d \rightarrow 2\text{cm}$ ), this is a time scale on the order of  $10^{10}$  years. However, if we were able to measure the separation of the particles to the accuracy of LIGO ( $\sim 10^{-22}\text{m}$ ), the associated timescale would be on the order of seconds! So, laboratory detection seems like it would be extremely challenging, but not necessarily impossible.

## Problem 2

- (a) Units of physical quantities form a  $\mathbb{Q}$ -vector space. Let's work in the Length, Mass, Time or  $\{\mathcal{L}, \mathcal{M}, \mathcal{T}\}$ . The units of the constants can then be expressed as

$$[c] = \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}, \quad [\hbar] = \begin{pmatrix} 2 \\ 1 \\ -1 \end{pmatrix}, \quad [G] = \begin{pmatrix} 3 \\ -1 \\ 2 \end{pmatrix}.$$

Calculating the units of the proposed quantities follows as

$$\begin{aligned} \left[ \frac{c^5}{\hbar G^2} \right] &= 5 \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} - \begin{pmatrix} 2 \\ 1 \\ -1 \end{pmatrix} - 2 \begin{pmatrix} 3 \\ -1 \\ 2 \end{pmatrix} \\ &= \begin{pmatrix} -3 \\ 1 \\ 0 \end{pmatrix} \\ &= \frac{\mathcal{M}}{\mathcal{L}^3}, \end{aligned}$$

and we can see the quantity indeed as units of mass density.

- (b) Plugging in the values of the constants and the observed vacuum energy density, we get a ration of  $\rho_\Lambda/\rho_{\text{Pl}} \approx 10^{-123}$ , as illustrated in Figure 1.

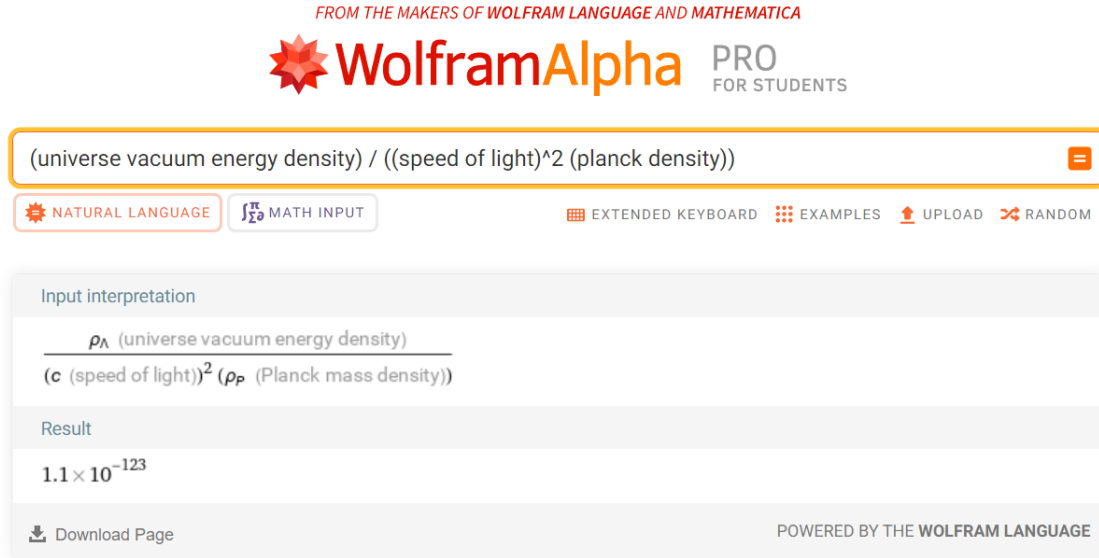

Figure 1: Calculation of  $\rho_\Lambda/\rho_{\text{Pl}}$  via WolframAlpha.

### Problem 3

- (a) Matter density is proportional to  $a^{-3}$ , and the temperature is proportional to  $a^{-1}$ , so

$$p \propto T\rho \implies \boxed{p \propto a^{-4}}$$

- (b) The energy of the neutrinos is proportional to their temperature, and we seek the temperature at which this energy is comparable to their rest mass. Therefore,

$$\frac{T}{T_0} \propto \left( \frac{a}{a_0} \right)^{-1} = \frac{a_0}{a} = z + 1$$

$$\Rightarrow z \approx \frac{T}{T_0} - 1 \approx \frac{m_\nu}{T_0} - 1 \approx \boxed{579}$$

FROM THE MAKERS OF WOLFRAM LANGUAGE AND MATHEMATICA

 **WolframAlpha** PRO  
FOR STUDENTS

0.1 eV / ((2 K) \*(boltzman constant)) - 1

Assuming electronvolts for "eV" | Use [electronvolts per speed of light squared](#) or [more](#) instead  
Assuming kelvins of absolute temperature for "K" | Use [kelvins difference](#) or [more](#) instead

Input interpretation

$$\frac{0.1 \text{ eV (electronvolts)}}{2 \text{ K (kelvins)} (k \text{ (Boltzmann constant)})} - 1$$

Result

579
